Daily Coding Problem #145

Problem

This problem was asked by Google.

Given the head of a singly linked list, swap every two nodes and return its head.

For example, given `1 -> 2 -> 3 -> 4`, return `2 -> 1 -> 4 -> 3`.

Solution

This problem can be solved either recursively or iteratively, and either by mutating `next` pointers or `val` values. The easiest implementation which yields the best space and time complexity is iteratively changing `val`.

In the following code, we maintain and see these properties:

- `curr` holds the current node that needs to be swapped with its `next` node.
- If `curr.next` is `None`, then there isn't anything to be swapped with, so the loop exits.
- In the loop, `curr` is able to jump to `curr.next.next` since we know `curr.next` exists.

```
def swap_every_two(node):
    curr = node

    while curr and curr.next:
        curr.val, curr.next.val = curr.next.val, curr.val

        curr = curr.next.next
    return node
```

This takes O(1) space and O(n) time.
